Abstract:

The Iron-based spin ladder BaFe₂Se₃ displays an exotic block-like magnetic state. Previous inelastic neutron scattering unveiled the connection between the block magnetic state and an orbital-selective Mott phase (OSMP). Besides, the electron doping of the OSMP could induce new block magnetic states. Thus, the Ni doping of BaFe₂Se₃ should change the magnetic structure of BaFe₂Se₃. We plan to use neutron powder diffraction to investigate this transformation which could help us understand the origin of the block magnetism and its relation to the OSMP. We have already measured the 0.5% Ni-doped one, the Neel temperature is decreased to 170 K. This time we want to measure the 1% doped one. We expect a further decrease in Neel temperature.

Doping induced change of magnetic structure in BaFe₂Se₃

- Objective & expected results :-

The main aim of this proposal was to perform powder neutron diffraction (PND) experiments on Ba(Fe_{0.99}Ni_{0.01})₂Se₃. By Rietveld refinements, the magnetic structure under different temperatures will be determined. Meanwhile, the transition temperature T_N will be clarified.

- Results and the conclusions of the study (main part): -

Recently, the Iron-based spin ladder BaFe₂Se₃ has attracted much attention due to its superconductivity under pressure. Besides, BaFe₂Se₃ displays an exotic block-like magnetic state which is unique in its family. Previous inelastic neutron scattering unveiled the connection between the block magnetic state and an orbital-selective Mott phase (OSMP). Besides, the electron doping of the OSMP could induce new block magnetic states. Thus, the Ni doping of BaFe₂Se₃ should change the magnetic structure of BaFe₂Se₃.

In this proposal, we used PND measurement to investigate the possible magnetic transformation on low doped compound Ba(Fe_{0.99}Ni_{0.01})₂Se₃. The sample was measured at the temperature range 2-300 K. By the Rietveld refinement, we can get the magnetic structure and the magnetic moment per Fe at each temperature. As shown in Figure 1, the block magnetic order persists up to 153 K. No obvious magnetic structural transition was observed. The present experiment shows that the low doped (1%) compound may not enough to change the magnetic order. Higher doped sample is need to be investigated.

Figure1: Temperature dependent of moment per Fe for Ba(Fe_{0.99}Ni_{0.01})₂Se₃. The data was extracted from the refinements of PND patterns.
